## PROCEEDINGS OF THE

Entomological Society of Washington

# ADDITIONS DURING 1956 AND 1957 TO THE WASP FAUNA OF LOST RIVER STATE PARK, WEST VIRGINIA, WITH BIOLOGICAL NOTES AND DESCRIPTIONS OF NEW SPECIES 

(Hymenoptera, Aculeata)<br>Karl V. Kromben, Entomology Research Division, U. S. Ifepartment of Agriculture, Washington, D. C.

The wasp fauna of Lost River State Park, Hardy County, West Virginia, has been the subject of several earlier papers (Krombein: Proc. Ent. Soc. Wash. 54: 175-184, 6 figs., 1952; Bul. Brooklyn Ent. Soc. 49 : 1-7. 1954: Proc. Ent. Soc. Wash. 58: 153-161, 3 figs., 1956). Those papers catalogued the wasp fama as it occurred early in the summer (June 18-25 and July 18, 1951; June 29-July 5, 1953; and July 4-11, 1955). About 80 species were taken during each of those years, and the cumulative total amounted to 128 species.

We were able to spend part of our family vacation in the Park in 1956 from August 21 to September 2, and again in 1957 from July 29 to August 11. The summer of 1956 was cooler and rainier than normal, and more species (120) were active than during earlier periods in preceding years. In contrast, extreme drought conditions prevailed during the summer of 1957 , and 82 species were collected. In 1956 I eollected 39 species not taken in previons years, and in 1957 there were 28 new to the Park list. Allowing for duplications in these two years, the faunal list now stands at 179 species in the families already listed. In addition, another family, the Chrysididae, has now been worked up, and the 12 species collected in the Park during these five years brings the grand total to 191.

In addition to the collection data presented below for the speeies not listed previously, I am recording a few biologieal notes, descriptions of three new species, Chrysis (Chrysis) cembricola, Methocha (Methocha) impolita and Gorytes (Gorytes) deceptor, a redescription of Spilomena albochpeata Bradley, and a description of the previonsly unknown male of Nitela cirginiensis Rohwer.

I am indebted to the following specialists for identification of the prey captured by several of the wasps: B. J. Kaston (Araneae), Kellie O'Neill (thysanopterons prey of Spilomena pusilla (Say)), and C. W. Sabrosky (Diptera).

## Additions to the Wasp Fauna <br> Family CHRYSIDIDAE

This family of cuckoo wasps was not included in the previous reports, so all collection data are given here.

Omalus iridescens (Norton). 1 ㅇ, July 18, 1951; 1 of, July 1, 1953; along trails.
Omalus laeviventris Cresson. 1 ¢, July 18, 1951; 1 ㅇ, June 30, 1953; 1 ó, Angust 26, 19.56; two of these taken along trails on vegetation.
Omalus sinuosus (Say). 1 ¢, Jume 21 and 1 of, July 18, 1951; ㅇ 9 , June 29 and July 5, 1953; 1 ㅇ, July 10, 1955; some of these taken on log cabin walls, others along trails.
Hedychridium dimidiatum Say. 2 ¢ ㅇ, June 30 and July 4, 1953; 1 ¢ , 2 ô ó,
 1957; along trails, mostly on ground but some on foliage.
Hedychridium fletcheri Bodenstein. 1 of, August 30, 1956; along trail.
Hedychrum violaceum Brullé. 5 ôo , June 30-July 4, 1953; 3 우, 4 ôô, July $5-10,1955 ; 18$, August 84,1956 ; mostly along trails, but a few on $\log$ cabin walls.
Chrysis (Chrysogona) verticalis Patton. 1 í, July 5, 1953; 2 q ㅇ, July 4-10,
 mostly along trails, but several on $\log$ cabin walls.
Chrysis (Trichrysis) parvula Fabricius. 1 ¢, June 24, 1951; 1 ¢, June 30, 1953; 2 웅, 3 ô ó, July 4-10, 1955; 2 웅, 1 ô, July 31-August 7, 1957; mostly on $\log$ cabin walls, but several along trails.
Chrysis (Chrysis) cembricola, new species. 6 오 오, June 19-24, 1951; 1 ㅇ, June 30,$1953 ; 6$ ¢ ¢ ¢, July 5-10, 1955; 1 ô, Angust 30, 1956; mostly on log cahin walls, but a few along trails including the single male.
Chrysis (Chrysis) chalcopyga Mocsáry. 12 우, June 18-ㄹ4, 1951; 1 ㅇ, July 1, 1953; 1 ㅇ, . July 99, 1957; mostly on $\log$ cabin walls, but a few along trails.
 August $\mathfrak{2}-97.1956 ; 1$ ㅇ, 1 of, August 7-11, 1957; mostly along trails, but at least one on $\log$ cabin wall.
Mesitiopterus kahlii Ashmead. 1 ô, Angust 28, 1956; along trail.

## Family BETHYLIDAE

Epyris sp. 1. 4 ô ô, August 2.5-29, 1956; 1 ㅇ, 8 ô of, August 1-10, 1957.
Anisepyris columbianus (Ashmead). 1 ; Angust ən, 1956. [Det. H. E. Evans].
Rhabdepyris sp. 1. ©, August 27, 1956
Holepyris sp. ㄹ 우, ㄴ ô ô; Augnst 25-29, 1956; ㄹ ô ô August 7-9, 1957.
Pseudisobrachium myrmecophilum (Aslimead). 1 ô, August 11, 1957; erawling on gravelly soil along trail edge. [Det. H. E. Evans].

## Family TIPHIIDAE

 gust 3-8, 1957.
Tiphia transversa Say. 1 o, August 3, 1957.
Tiphia sp. 1. 1 ¢, 19 ô $\hat{\delta}$, August 6-7, 1957; on ground and flying low over ground in an area of two square meters.

Methocha (Methocha) impolita, new species. 1 \&, August 8, 1957; erawling in sun on gravelly soil along trail edge.
Myrmosa (Myrmosa) blakei Bradley. 1 ㅇ, August 25, 1956; 1 ㅇ, August 7, 1957; crawling on gravelly soil at trail edge.

## Family MUTILLIDAE

Dasymutilla vesta vesta (Cresson). 1 \& August 3, 1957.
Ephuta pauxilla pauxilla Bradley. 2 ô $\hat{\delta}$, August $23-25$, 1956; on foliage along trail.
Ephuta scrupea (Say). 5 ô ô, August 23-29, 1956; along trail on foliage. I recorded a female of this species as conchate Mickel in 1956. The latter species should be deleted from the Park list.

## Family VEspidae

Zethus (Zethusculus) spinipes spinipes Say. 1 ㅇ, August 11, 1957.
Stenodynerus (Stenodynerus) blepharus Bohart. 1 §, August 26, 1956.

## Family POMPILIDAE

Priocnemioides unifasciatus unifasciatus (Say). 1 ô, August 29, 1956; crawling over leaf litter in open woods.
Dipogon (Dipogon) brevis brevis (Cresson). 1 \}̂, August 27, 1956.
Dipogon (Dipogon) brevis recalvus Townes. 2 ô ô, August 24-25, 1956. This and the preceding species were taken within several hundred feet of each other in identical habitats. I wonder if this does not indicate that recalcus is aetually a distinct speeies rather than a subspecies of brevis.
Priocnemis (Priocnemis) hestia (Banks). 9 우, 5 of ठ, August 23-29, 1956; 1 ठ, July 29, 1957; in open woods flying among undergrowth.
Auplopus caerulescens subcorticalis (Walsh). 3 ¢ 9,2 ô $\hat{6}$, August 23-26, 1956; 1 ㅇ, 1 ô, August 6-7, 1957.
Ageniella (Ageniella) cupida (Cresson). 1 \&, August $28,1956$.
Ageniella (Ageniella) norata Banks. 14 ¢ ㅇ, 56 ô $\hat{\delta}$, August $2 \Omega-29,1956 ; 1$ ô, August 7,1957 ; mostly taken in open woods flying among undergrowth.
Ageniella (Ageniella) partita Banks. 1 \&, August 29, 1956.
Ageniella (Ageniella) sp. 1 ㅇ, August 29, 1956; 1 ㅇ, August 10, 1957. This is possibly the unknown female of mintaka Brimley which has been taken in the Park in two previous years.
Ageniella (Priophanes) agenioides (Fox). 1 \&, August 28, 1955.
Ceropales hatoda Brimley. ㄴ ¢ $\ddagger, 4$ ô ô, August $26-30,1956 ; 1$ ㅇ, ㅇ ô ô, July 31-August 10, 1957.
Evagetes subangulatus (Banks). 1 \&, August 29, 1956.
Tachypompilus ferrugineus nigrescens (Banks). 1 \& , August 28, 1956; in clearing in open woods.
Aporinellus taeniatus wheeleri Bequaert. 1 \&, August 30, 19.76; on gravelly path.

## Family AMPULICIDAE

Ampulex (Rhinopsis) canaliculata Say. 1 \&, August 26, 1956; on rail fence.

## Family SPHECIDAE

Astata (Astata) leuthstromi Ashmead. 2 우우, August 23-25, 1956; 2 우, 1 ô, August 1-9, 1957; on gravelly soil along trail edge in sun.
Astata (Astata) nubecula Cresson. 3 오 우, August 23-25, 1956; 1 ㅇ, August 10, 1957; on gravelly soil along trail edge in sun.
Solierella plenoculoides plenoculoides (Fox). 2 우, 1 ㅇ, August 26-30, 19.56; $\because \quad$ 오 ㅇ, July 30, 1951; on gravelly path.
Nitela virginiensis Rohwer. 3 ㅇ 9,1 §, August 24-97, 1956.
Tachysphex sepulcralis Williams. 3 ô ô, August 24-2S, 1956; ou gravelly path.
Tachysphex n. sp. 1. ㄹㅇㅇㅇ, August 26-30, 1956; on gravelly path.
Tachysphex n. sp. 2. 1 ô, August 30,$1956 ; 3$ ô ó, August 3-11, 1957; on gravelly path.
Motes (Notogonius) argentata (Beauvois). 1 \&, 1 d, August $-4-9.5,1956 ; 1$ ㅇ, August 8, 1957; on gravelly path.
Trypoxylon (Trypargilum) tridentatum Packard. 1 \&, August 9, 1957.
Psen (Psen) erythropoda Roliwer. 1 \&, July 31, 1957.
Mimesa (Mimesa) pauper Packard. 1 ô, August 6, 1957.
Stigmus (Stigmus) inordinatus universitatus Rohwer. 3 오오, August 27 - September 1, 1956; 1 ㅇ, August 9, 1957; along trail through open woods. This species was not known previously from east of Colorado.
Spilomena alboclypeata Bradley. 1 ㅇ, August 24 , 1956 ; crawling on $\log$ of cabin wall in sun.
 1, 1957.
Sphex urnarius urnarius (Dablbom). 1 d, August $26,1956$.
Nysson (Nysson) lateralis Packard. 4 ㅇㅇ, 1 of, August 24-27, 1956; 9 ㅇ¢, August 1-11, 1957; on gravelly soil along trail edge in sun.
Lestiphorus cockerelli (Rohwer). 1 \&, August 26, 1956; on oak foliage in sun.
Gorytes (Gorytes) deceptor, new species. 3 \& ㅇ, July 31-August 8, 1957.
Crabro (Crabro) discretus Fox. 1 \&, August 29, 1956; 2 \& $\%$, July 31 -August 1, 1957; on trail through open woods.
Ectemnius (Ectemnius) brunneipes (Packard). 1 ㅇ, August 26, 1956.
Oxybelus decorosum Mickel. 4 ô ô, July 30-August 6, 19.57; on gravelly path.

## Biological Notes

## Family POMPILIDAE

## Dipogon (Deuteragenia) sayi sayi Banks

A female ( 73057 A ), 7.5 mm . long, was captured with her paralyzed spider prey on vegetation at the edge of a clearing in the woods, July 30, 1957. The spider was an adult female thomisid, Tysticus fraternus Banks, 5.1 mm . long.

## Calicurgus hyalinatus alienatus (Smith)

One female ( 8357 A ), 6.3 mm . long, was taken on August 3, 1957. She was pulling her paralyzed spider prey beneath some leaf litter at the edge of a trail exposed to the full sun. The spider was a male araneid in the penultimate instar, Araneus marmoreus Clerck, 6.1 mm . long.

A second female ( 8857 A ), 5.7 mm . long, was captured while she was transporting her paralyzed spider prey in a similar habitat on August 8, 1957. The spider was a male araneid in the penultimate instar, probably of a species of Neoscona, 4.1 mm . long.

## Anoplius (Lophopompilus) carolina (Banks)

A slightly worn female ( 82856 A ), 12 mm . long, was captured August 28, 1956, on a trail through the woods in dense shade. She was walking backward over the trail, dragging a large paralyzed spider, which she held by the hind coxae in her mandibles. The spider was a mature male agelenid, Wadotes hybridus (Emertom), 13 mm . long.

## Family SPHECIDAE

Spilomena pusilla (Say)
A slightly worn female ( 83056 A ), 2. 4 mm . long, was collected August 30, 1956, as she walked on a $\log$ in the cabin wall in the sun near the entrance to her burrow. She held in her mandibles a paralyzed immature thrips 0.72 mm . long. The nymph was probably in the second instar and appeared to belong to the variabilis (Beach) section of the genus Sericothrips.

## Euplilis (Corynopus) coarctatus modestus (Rohwer)

A newly emerged pair ( 82656 A ) was taken in copula on oak foliage at the edge of a trail through open woods on August $26,1956$.

## Crabro (Crabro) discretus Fox

A somewhat worn female $(8: 956 \mathrm{~A}), 11.5 \mathrm{~mm}$. long, was captured on the ground August 29,1956 , on a trail through open woods. She was struggling to get into the air with her prey, a large, paralyzed male larvaevorid, Achaetoneura sp. (possibly aletiae Riley), which was $1:$ mm. long and much bulkier than the wasp.

## Taxonomic Notes

## Family CHRYSIDIDAE

Chrysis (Chrysis) cembricola, new species
(Figure 1)
This rather small, slender Chrysis is seemingly closer to chalcopyga Mocsáry ( $=$ nitidula anctt. not F.) than to any other species in the Nearctic fama. Such characters as the relative length of the head and pronotmm, sculpture of frontal concavity, and shape of the lateral and apical margins of the third abdominal tergum cause it to run to nitidula in Aaron's key to the North American species (Trans. Amer. Ent. Soc. 12: 232-233, 1885). However, it is distinguished at once from chalcopyga by its smaller size ( 7.5 mm . as against 9.5 mm . average length), the different head length :width ratio ( 0.56 as compared to 0.45 ), first and second abdominal terga with the punctures mostly separated instead of confluent in longitudinal rows medianly on the first and basal half of second, and the ocelli in an equilateral triangle instead of a lower, flattened triangle.

Fig. 1, Chrysis cembricola, female, dorsum of head and pronotum; figs. 2-4, Spilomena spp., frontal view of male lieads, figs. 2a-4a, same of female heads; figs. 2, 2a, S. pusilla; figs. 3, 3a, S. ampliceps; figs. 4, 4a, alboclypeata; fig. 5, S. pusilla, lateral view of female pronotum; fig. 6, S. alboclypeata, the same. (Drawings by A. D. Cushman; fig. 1 is 22 X , figs. $2-6,44 \mathrm{X}$; specimens for figs. 1, 2, 3, 5 from Lost River St. Pk., W. Va., for figs. 4, 6 from Arlington, Ta.)

Type. $\ddagger$; Lost River State Park, W. Va.; July 5, 1955 (K. V. Krombein; on $\log$ cabin wall in sun) [U. S. National Museum, Type No. 63508 ; by donation from author's collection].

Length 7.4 mm ., forewing including tegula 5.4 mm . Mostly metallic blue, the frontal concavity, temples, legs and venter with bright green reflections in certain aspects; tarsi dark brown and flagellum black beyond second segment. Wings clear, the anterior edge of marginal cell narrowly infumated, the reins dark brown. Pubescence generally short, erect and inconspicuous; light brown on dorsum of head and thorax, somewhat longer and pale on sides of head and thorax, and thoracic venter; very short, suberect, denser and pale on abrominal dorsum.

Head in frontal aspect with the width 1.1 times the height, the interocular distance at level of facial carina 0.45 times the head width; in dorsal view (fig. 1) the length from facial carina to occiput 0.56 times the head width and subequal to interocular distance at level of posterior ocelli; mandille without an inner tooth; clypeus with median length subequal to diameter of antennal fossa, tumid medianly, the apical margin broadly and shallowly emarginate for a distance equal to half the total width, with scattered punctures except a narrow apical rim smooth; facial concavity with height subequal to width, moderately concave, closely punctate, the punctures becoming progressively larger toward the facial carina; the latter not as strong and sharp as in chalcopyga, four fifths the interocular distance at that level, the central three-fourths of the carina bowed slightly downward in middle, the extreme sides of carina turned downward at a very obtuse angle; dorsum of head with rather coarse, close punctures and a narrow smooth strip laterad of each hind ocellus; ocellar triangle equilateral, situated a little closer to facial carina than to occiput, only slightly raised, the lateral ocelli directed obliquely outward but not situated in pits; ocellocular line subequal to postocellar line; malar space very short, 0.6 times the length of antennal pedicel; temporal carina extending upward from base of mandible to a point opposite the facial carina; relative lengths of first four antennal segmnts as $5: 2: 3: 2$.

Pronotum (fig. 1) at humeri 0.8 times the head width, the median length of disk one-third the humeral width and half the head length from facial carina to occiput; humeri not projecting, right-angled as viewed from above; prehumeral slope almost perpendicular and with small close punctures except for a small smooth median area which is oblique; pronotal disk with larger, mostly subcontiguous pumetures, such interspaces as are present with a few minute punctures, small depressed area at middle anteriorly; lateral margins of pronotum straight and slightly divergent posteriorly so that posterior width is 1.1 times the humeral width ; lateral surface of pronotum with fine irregular rugulae and without a pit; scutum with length two-thirds the width, the surface with coarse, contiguous pmetures, notaulices well-developed, subparallel, the parapsidal furrows slightly convergent posteriorly, weak and present on apical two-thirds only; scutellum feebly convex, two thirds as long as scutum, with large, shallow, contiguous pits; postscutellum more strongly convex, two-thirds as long as scutellum, sculpture as on scutum; mesopleuron divided into upper and lower plates by a series of foreae which intersect an oblique series of foreae, a rather large, shallow, smooth depressed area at the intersection; metapleural spine acute, short, barely reaching lase of posterolateral propodeal projection; propodeum obliquely declivous posteriorly, viewed
from above the posterolateral projections are short and acutely angulate (about $60^{\circ}$ ); U-shaped groove of propodeal dorsum relatively broad, crossed by a few weak carina, the area enclosed by groove sculptured like postscutellum.

Relative median lengths of abdominal terga as $7: 15: 6$; first tergum with a broad shallow depression anteriorly, with moterately large punctures which are more or less separated except laterally where they are confluent and somewhat larger and deeper, discally with scattered minute punctures also; width of second tergum three-fourths the median length and one and one-half times the length of lateral margin, the posterolateral angles extending below anterolateral edge of third tergum ; large punctures of second tergm smaller than those of first, separated more widely along posterior margin than elsewhere but not confluent anywhere, and with a very few scattered minute pmotures, the apical margin slightly thickened; third tergum with lateral margins straight, apical margin with teeth short and obtuse, separated by shallow emarginations, the lateral and median teeth closer to each other than the two median teeth; punctures of third tergum about equal in size to those on second but mostly confluent; submarginal foveate groove extending two-thirds of distance to base of third tergnm, the foveae not deeply impressed, about eight on a side.

Allotype. os ; Lost River State l'ark, W. Va.; Angust 30, 1956 (K. Y. Krombem; along trail through woods) [USNM].

Length 6.0 mm ., forewing including tegula 4.0 mm . Color as in female except more purplish and with no green reflections, center of second tergum blackish, flagellum black beyond first segment. Wings and vestiture as in female. Sculpture and body proportions similar to female except as follows: facial carina evanescent; first flagellar segment relatively shorter, only slightly longer than second; submarginal foveate groove of third tergum with the groove evanescent laterally and represented by only a few small pits; apical teeth of third tergum shorter and right-angled.

Paratypes. 12 ㅇ 우 ; same data as type but June 19, 22, 23 and 24, 1951, June 30, 1953, and July 5, 6, 9 and 10, 19.5. (K. V. Krombein; mostly on logs on cabin walls). 12 오 오 : Arlington, Ya., Jume 14, 1952 (1 ㅇ ), June 21 and September 7, 1953 (2 ㅇ ㅇ), May 22 and 31, 1954 ( 2 오 ) , and April 29 ( 1 \& reared from wooden trap nest K 11 of Symmorphus canadensis (Saussure), May 26 (3 of of), May 30 (2 ㅇ \& ) and June 2 ( 1 ㅇ) , 1957 ( $\mathrm{K} . \mathrm{V}$. Krombein; on wooden walls of old cowshed). 1 \& ; Dumn Loring, Fairfax Co., W. Va.; September 11, 1954 (K. V. Krombein; on honeydew secretions of Toumeyella liriodendri ((imel.) on foliage of Liriodendron tulipifera). 3 ㅇ 울 Westmoreland State Park, Westmoreland Co., Va.; July 4 and 8, 1951 (K. V. Krombein). 1 우; Brookland, Washington, D. C.; May 15, 1908 (R. W. Van Horn; bred from hickory) [USNM]. 1 \& ; Washington, D.C.; May 28, 1944 (G. E. Bohart) [GEB]. 1 \& ; Washington, D. C.; July 12, 1927 (lot no. 3978) [USNM]. 2 와 오 Biltmore, Buncombe Co., N. C., June 10, 1924 (R. A. St. George) [USNM]. 1 \& ; Harrisburg, Danphin Co., Pa.; June 17, 1916 (W. S. Fisher; on hickory) [USNAI]. 1 ㅇ ; Overbrook, Philadelphia Co., Pa.; August 16, 1914
(G. M. Greene) [USNM]. Paratypes are in the L. S. National Mnsemm and personal collections of K. W. Cooper, G. E. Pohart and the author.

About half of the paratypes have some greenish reflections on head and thorax. They are quite similar to the type in other details of the color, scupture and pubescence, and are 5.9-7.8 mm. long.

Biology. One female of cembricold was reared at Arlington, Va., from a wooden trap nest ( K 11) provisioned by the solitary vespid, symmorphus canadensis (Saussure). This trap nest contained a boring 70 mm . long with a diameter of 3 mm . It was set out in a horizontal position two meters above the ground on the wooden wall of an old cowshed on June $24,19 \mathbf{D}^{-} 6$. The host wasp completed her nest four days later. I split open the nest on .June 30 and found two stored cells at the imer end, 19 and 21 mm . long respectively, separated by clay partitions and with an empty vestibular cell 18 mm. long between cell 2 and the closing clay phug at the entrance. The eells were stored with paralyzed larvae of the chrrsomelid leaf-miner in lorust, Chalepus dorsalis Thumberg. The egrg of the vespid was attached by a slender thread to the ceiling at the immer end of each cell, that in cell 1 beine shriveled. I did not see the ehresidid larva in cell 1 on . June 30, but presumably it had sucked out the fluid contents of the host ecrg before heginning to feed on the stored prey as is customary with some other species of Chrysididae. On July J the chrysidid larva was begimning to spin its cocoon, and the Symmorphus larva in cell 2 was almost full gown. ${ }^{1}$ The chrysidid larva coated the cell walls and ends with transparent silk. Then it spun a cocoon of transparent silk, almost 3 mm . in diameter and 6 mm . long. with rounded ends and with two small opaque patches of dense white silk near the onter end. I inspected this nest periodically during the next several months but the chrysidid remained in the prepupal state throngh October 8. On October 12 1 placed all my trap nests outdoors for winter storage and brought them into my office again on April 20, 19.57. I made the first inspection of these over-wintering traps on April 22 , and fomd a pale pupa with black eyes in this cocoon. My experience has been that e-3 days after pupation are required before a chrysidid pupa reaches the black-eyed stage. so this individual must have pupated not later than April 20. On April 26 there was a fully colored pupa in the eocoon. The adult wasp had cut through the cocoon and emerged when [ opened the nest on April 29. Adult Symmorphus canadensis emerged from other trap nests kept under similar conditions from May 14 to 26 .

It is probable that combricola press only on wasps nesting in preexisting cavities in wood. Of the specimens in the trpe series nine of the thirteen females at Lost River State Park, W'. V'a., and all three females at Westmoreland State Park, Va., were taken on logs forming

[^0]the cabin walls, and all twelve females at Arlington, Va., were taken on the wooden wall of an old cowshed. There were a number of species of wasps nesting in abandoned beetle burrows or other cavities in the logs or wood in each of these three localities, but the wasp that was most abumdant and suitable in size to serve as a host for the chrysidid in each locality was symmorphus comadensis. It seems likely that this respid may prove eventually to be one of the chief hosts of the chrysidid. I looked over the material of N!mmorphus comadcnsis in the U. S. National Musem and fonnd four females and two males bearing the same label data as the Biltmore, N. C'., paratypes of cembricola, and one female with the same label data as the Washington, D. C. (lot no. 3978), paratype of cembricola. There are no label data indicating a parasite-host relationship, but the identical label data sugqest the possibility that the specimens might have occurred in the same restricted habitat.

The rather limited collection and rearing data suggest that combricolu has successfully adjusted its developmental cycle to that of symmorphus canadonsis. The symmorphus population nesting in mys cowshed in Arlington is ahmost entirely univoltine as demonstrated by trap nest rearings and seasonal flight range. The population of the chrysidid at the same locality is largely mivoltine as evidenced by similar data. Howerer, occasionally there may be a very small partial second generation of both canadensis and cembricola. Symmorphus was active during all our visits to Lost River State Park, but with noticeably higher population levels earlier in the season, indicating at least a partial second qeneration. All of the female cembricola at the Park were taken during periods coinciding with the population peak of Symmorphus, and the capture of a male at the end of August suggests at least a partial second generation of the chrysidid.

## Family TIPHIIDAE

Methocha (Methocha) impolita, new species
The female of this species is one of the most distinctive of the Nearctic forms, and may be recognized at once by the dull, roughened integrment of the head and thorax as contrasted to the highly polished, smooth integument of the other known species of this region. In addition, the following combination of characters will serve to distinguish it from its congeners: the very short malar space ( 0.09 times the eye height) ; the front almost flat between the eyes; moderately gibbose scutum and scutellum; blunt mesosternal teeth; and basal and apical abdominal segments red, the intervening segments black in part or almost entirely. M. stygia (Say), the only species now known to occur within the range of impolita, has a longer malar space ( 0.18 times the eye height), the front rounded between eyes, the mesosternal teeth acute, and the abdomen is rarely so colored, usually being either entirely black, or entirely red, or with the base only red. The male of impolita is unknown.

1. impolita has been collected in Lost River State Park, IV. Ya., at or near Washington, D. C., and at Ithaca, N. Y. The three specimens which I collected were all taken in open, smny areas, on soils having a high content of gravel or larger stones. D. G. Shappirio informs me that the single specimen captured by him was from a similar soil type.

Type. \& ; Lost River State Park, W. Va.; August 8, 1957 (K. V. Krombein ; crawling in sun on gravelly soil along trail) [U. S. National Museum. Type No. 64088 ; by donation from anthor's collection].

Length $\overline{7} .4 \mathrm{~mm}$. Head black, mandibles and basal seven antemal segments red ; legs red except for some infuscation on femora above at apex, on tibiae outwardly and the last segmenti of all tarsi; aldomen red, the second to fourth terga with black bands covering the posterior half or two-thirds of these segments except for extreme apices, the bands broader along midline and narrowed toward sides, the posterior margins straight, the anterior margins areuate. Pubeseence quite sparse, pale golden on head and thoracie dorsum, silvery on rest of thorax, legs and abdomen.

Head dull, strongly narrowed behind eyes, its greatest width 2.2 times the width at occipital carina; clypeus tumid in middle above the wide, depressed apical rim but not tuberculate there; malar space very short, 0.09 times the eye height; front almost flat letween eves; front and vertex with the integument finely shagreened, and with scattered large punctures which are closer between ocellar triangle and eves than elsewhere; least interocular distance half the head width; ocelli in a compact right-angled triangle, the ocellocular distance 1.6 times the posterior interocellar distance.

Thorax dull; pronotum along midline as long as combined lengths of scutum, scutellum and postscutellum, in profile strongly rounded, the surface finely shagreened and with a few scattered punctures and with some very close and fine. longitudinal wrinkles dorsally; scutum and scutelhm subequal in length, gibbose, in profile the sentum separated from pronotum by a right-angled noteh, the surface finely shagreened; mesopleuron finely shagreened and with a few oblique rugae ahose posteriorly; mesosternum with a pair of erect blunt teeth in front of mid coxac; metasternum with a pair of acute teeth in front of hind coxae; propodeum finely shagreened, dorsally with very close and fine, longitudinal wrinkles, posteriorly with half a dozen arcuate carinat above athominal insertion, and laterally with fine, close oblique wrinkles.

Ablomen shining and with a few seattered fine punctures; first sternite with a median groove on basal two-thirds.

Male. Unknown.
Paratypes. 2 ㅇ 9 ; Dunn Loring, Fairfax Co., Va.; June 26, 1949, and July 26,1947 (K. V. Krombein; crawling on clayey soil having a high gravel content in an area open to sum) [KVK]. 1 o; C'lifton, Fairfax Co., Va.; June 9, 1933 (.J. C. Bridwell) [USNM]. 1 if ; Rock (reek Park, Washington, D. C.; June 26, 1947 (D. G. Shappirio) [DGS]. 1 of: Van Nata's Dam, Ithaca, Tompkins C'o., N. Y.; July 20, 1931 (P. P. Babiy) [CU].

The paratypes vary in leneth from $\overline{5} .1$ to 8.7 mm . The color ako shows considerable variation as follows : in the specimens with the most red (Clifton and Dumn Loring) the head and thorax are as in type but the leas are all red and the black stripes on second to fourth terga are narrower and do not extend as far laterad; in the specimens with the least red (Washington and Ithaca) the head, thorax and legs are as in type but the second to fourth terga are all black except for extreme base of second. narru apices of each, and small anterolateral areas on third and fourth. The vestiture and body proportions are quite similar. The senlpture variss somewhat as follows: the smallest specimen (Dnnn Loring) lacks the fine close wrinkles on pronotum and propodeum as does the Ithaca specimen, and the next to the smallest (Washington) lacks them on propodeum; and the two largest (Clifton and Dumn Loring) have a few oblique to arenate wrinkles on wibbose part of seutum.

## Family SPHECIDAE

## Nitela virginiensis Rohwer

The male of this species has not been reported previonsly. It is extremely similar to the female in details of the scolpture, color and restiture, and, aside from secondary sexual characters, it differs only in being a bit smaller, 3.5 mm . long. Neither the legs nor antennae bear any sexual modifications. The seventh sternmm has the surfare ronvex and rlothed with moderately dense, short erect hair, and the apical margin is broadly and shallowly emarginate; the preceding sterna do mot bear modified vestiture.

Spilomena alboclypeata Bradley
(Figures 4, 4a, 6)
This speries has not been recognized since its description fifty years ago from a mique male from British Columbia. Some time during the intervening years the head of the type was lost. The original deseription is very brief and fails to give the facial maculations in precise detail, so that the exact identification remained in donbt until I had an opportunity recently to dissect the genitialia from the type. A study of these and of the extermal eharacters of the thorax and abdomen enabled me to identify as alboclypeata a short series of males and a much larger series of associated females from British Columbia. Oregon, California, Idaho, Montana, Utah, Arizona, New Mexico, Colorado, Kansas, West Virginia and Virginia. I am giving a redescription of the male below, as well as a description of the hitherto unknown female, and also a key for the separation of the three species of Spilomena known from Lost River State Park.

Marginal cell of forewing with scattered minute setae; pronotum with a delicate carina extending from side of pronotal disk onto pronotal lobe; propodeal dorsum with a broad U-shaped area delimited by a sharp carina. FEMALE: greatest witth of temple 1.3 times eye width; face (fig. 3a) delicately but
noticeably lineolate, quite shiny. MALE: lower half of face yellow (fig. 3) ; flagellum testaceous except apical segment, clothed with appressed setae; third and fourth abdominal sterna with appressed short setae on apical third or half
ampliceps. Krombein
Marginal cell of forewing devoid of setae; pronotum (fig. 5) with a delicate carina extending from side of pronotal disk onto pronotal lobe; propodeal dorsum with a broad $C^{+}$-shaped area delimited by a sharp carina. FEMALE: greatest width of temple subequal to eye width; face delicately and noticeably lineolate, rather dull (fig. ©a). MALE: face yellow in middle for only a short distance above clypens, the sides more broadly yellow (fig. S) ; flagellum dark, elothed with appressed setae; third and fourth sterna with very narrow hands of dense, short appressed setae at apices
pusilla (Say)
Marginal eell of forewing devoid of setae; pronotum (fig. 6) without such a carina; U-shaped area on propodeal dorsnm without marginal carina. FEMALE: greatest width of temple subequal to eye width; face very shiny, the lineolations evaneseent (fig. 4a). MALE: face immaculate above middle of clypeus, the sides with a moderately large, subtriangular, pale yellow to white spot (fig. 4); flagellum dark, elothed with denser suberect setae; third and fourth sterna with sparser, appressed setae on apical half or more

Female. Length :..--2. 8 mm ., forewing including tegula $1.6-2.8 \mathrm{~mm}$. Black, withont metallic reflections; mandible light red, the base and apex darker; tegula trans parent, testaceous; legs varying from almost completely testacous except coxae to the following condition-apices narrowly of trochanters and femora, and hases and apiees of mid and hind thbiae, fore tibia, and tarsi except apical segment, testaceous. Pubescence short amb inconspichous, sibery; extremely sparse and short on front and mesopleuron; a little lenser on seutum, seutellum and last three abdominal segments; denser, though still relatively sparse, on mesosternum. Wings clear hyaline with violaceons reflections, sparsely setose, the marginal cell of forewing bare; stigma dark brown; reins pale to darker testaceous.

Head rery shiny, the lineolation delicate and evanescent; in frontal view (fig. 4a) subeireular, the height and width subequal: viewed from above the width twice the length, and vertex as long as torsal eye length; in lateral view the temple slightly angulate opposite middle of eye, its greatest width a bit greater than eye width; antennal scape 0.6 times as long as elypeal width at anterior mandibular condyles; postocellar distance 0.8 times the ocelloccipital distance and 0.7 times the ocellocular distance; elypeus tumid in middle, but withont a sharply defined trigonal platform, the margin of median lobe slightly emarginate; lower third of front with a very delicate median carina which is gradually evanescent above, and which extends slightly downward onto elypens.

Thorax except propodeum, rery shiny; pronotum dorsally with a strong, complete carina, viewed from laterally not produced upward into a tootl, no delicate carina extending from side of pronotal disk onto pronotal lobe (fig. 6) ; scutum and scutellum more noticeably lincolate than front, with scattered minute punctures discernible at 68 diameters, notanlices as long as in pusilla but not so strongly impressed; mesopleuron smooth with a few tiny punctures, epistermal suture minutely foreolate; propotemm dull, the dorsal surface with a pair of
longitudinal earinat near midline converging slightly toward apex; broad U-shaped area on propodeal dorsum not margined by a carina, the surface with fine and moderately close, transverse earinae; lateral propodeal surface separated from dorsal and posterior surfaces by a fine carina, the surface with oblique separated earinae: posterior surface with delicate, more or less transverse carinae and a stronger median carina on lower half.

Secont submarginal cell of forewing about threefourths as wide above as below, the width above subequal to height of cell; first recurrent nervure received near apex of first sulmarginal cell or interstitial with first transverse cubital vein.
legs and abdomen without noteworthy modifications.
Watt. Length -コ.1-』. 6 mm ., forewing including tegula $1.5-1.9 \mathrm{~mm}$. Black, without metallic reflections; the following testaccons-tegula, fore leg except coxa and usually the fore tibia outwardly, mid and hind femora and hind tibia narrowly ammulate at base and apex, mid tibia entirely, mid and hind tarsi except apical segment; the following varying from white to pale yellow-mandible except apical teeth which are light red, clypens, malar space, postmandibular triangle, a triangular spot on side of face extending upward along eye margin two-fifths of distance to anterior ocellus, and antennal scape. Pubescence as in female exeept antennal fiagellum clothed with rather dense, suberect short setae, and apical half of third abdominal sternum and all of fourth sternum with moderately dense, short appressed setae. Wings as in female.

Head seulptured as in female, in frontal view the width slightly greater than height ( 1.06 times) (fig. 4); viewed from above the width 2.2 times the length, and rertex a little shorter than dorsal eye length; in lateral view the temple slightly angulate opposite middle of eye, its greatest width subequal to eye width: antemal scape 0.6 times as long as elypeal width at anterior mandibular condyles; ocellocular and ocellocripital distances subequal, the postocellar distance 0.7 times as great: lower fourth of front with a very weak median carina which does mot extend downward onto clypeus.

Thorax and abdomen mueh as in female except for vestiture on third and fourth sterua.

Legs without modifications.
Senation similar to that of female except second submarginal cell of forewing about five-sixths as wide above as below, the width above subequal to height of cell.

Three of the females $(82253 \mathrm{C}, 83053 \mathrm{~A}$, and 92653 B$)$ captured in Arlington, Va., were taken with prey. Each was taken near her burrow entrance in a board in a cowshed wall. Each was carrying a paralyzed, immature, pale green thrips in her mandibles. Two of the specimens of prey were lost before being measured, but the third $(92653 \mathrm{~B})$ was 0.84 mm . in length. Females were active from at least 1000 to 1730 hours in Arlington, and were taken in May, July, Angust and September in 195.3 and 1954.

Gorytes (Gorytes) deceptor, new species
This is extremely similar to simillimus Smith in size, seneral color pattern and seulpture, but differs consistently in certain details of the
color and sculpture, and apparently also in the preferred pres. Th simillimus the upper sector of the metapleural-propodeal suture is foveolate, while in deceptor this part of the suture is a faint simple impression. The propodeal sculpture also separates the two at once: both sexes of simillimus have the rugae confined to the extreme base of the enclosure and to a small area adjacent to insertions of the abdomen and hind coxae; in deeeptor the propodeal enclosure is entirely longitudinally rugose in the male and on the basal half or more in the female, and both sexes have a much more extensive area of the posterior surface rugose. The most noticeable differences in color are as follows: the palpi are yellow except basal segment in deceptor, entirely fuscous in simillimus; in the female of deceptor the antennal flagellum and mid and hind trochanters are yellow beneath, while in simillimus the apical segments of the flagellum and all trochanters are dark beneath; in deceplor males the trochanters are yellow beneath but in simillimns they are dark. I am indebted to I. II. II. Yarrow of the British Musemm for comparison of material with the type of simillimus Smith.

There are two published records of simillimus preying on adult Cicadellidae in Buffalo, N. Y., and in Westmoreland State I'ark. Va. (Krombein: Ent. News 47: 93, 1936 and Trans. Amer. Ent. Soc. 78 : 95,1952 ). K. W. Cooper captured a female of deceptor at Princeton. N. J., transporting an adult membracid.
G. deceptor is known at present from a more circumseribed geographic range than is simillimus, but additional collecting may prove them to be coextensive. Both species fly together at Lost River State Park. There are definite records of deceptor from New Hampshire, Commeticut, New York, New Jersey, Virginia, West Virginia, Ontario, Michigan, Mimesota, Kansas and Nebraska. Published records indicate that simillimus oceurs from Nova Scotia, New Brunswick and Mane south to Georgia, and in Ontario, Michigan, Illinois, Nebraska, and British Columbia. It is possible that some of these records for simillimus may be based on misidentifications.

Type. 9 ; Lost River State Park. W. Va.; July 31, 1957 (K. V. Krombein) [U. S. National Musemm, Type No. 64095; by donation from author's collection].

Length 10.5 mm ., forewing 8.5 mm . Black and shining, the following lemon yellow: palpi except hasal segment, base of mandible, clypeus except very narrow apical margin, supraclypeal area except subantemal sutures, narrow stripe along lower two-thirds of imer eye margin, antema beneath, narrow stripe on pronotal dorsmm, posterior half of pronotal lobe, small spot on mesopleuron below base of forewing, hand on posterior half of scutelhm, a round spot on each side of propodeal enclosure behind spiracle, apical hands on first five terga, that on first covering the posterior third and with a deep right-angled emargination anteriorly toward middle, the remaining lands narrower, small posterolateral spots on second to fifth sterna which become progressively smaller toward apex, apices of all coxae beneath, all trochanters beneath, femora within on apical fourth or more, tihiae
except in varying amounts beneath, and fore and mid tarsi. Wings with a faint yellowish cast, the marginal cell somewhat infuscated; veins fuscous.

Sculpture and hody proportions very similar to simillimus. Front rather dull from dense fine punctures and with some seattered superimposed larger ones; vertex and thorax except proporleum with minute, well-separated pumetures; metapleural-propodeal suture well-marked on lower two-thirds, evanescent above; propodeal enclosure delimited by foveolate grooves, with a narrow central furrow on either side of which are ahout ten longitudinal rugat on the hasal two-thirds; posterior surfice of propotem and area ahove hind coxa with some vertical rugae extending about halfway to upper horizontal surface; pygidim triangular, mather narrow, the hasal width about two-thirds the length, the surface shining and with scattered, morlerately small punctures.

Lllotype. ó ; Kochester, Monroe Co.. N. Y. ; June 19:39 [ TSNM].
Length 10.1 mm ., forewing 7.6 mm . ('olor pattern similar to type with following exceptions: clypeus all yellow, flagellum dark beneath, first sternum with narrow apical band, secoml and third sterna with lateral spots comected by a broader hand, apices of coxae and trochanters entirely yellow beneath.

Sulptare and body proportions as in type except as follows: narrow longitudinal tyloides on first fou flagellar segments as in simillimus; propodeal enclosure cutirely rugose and posterior surface covered with vertical rugae, the lateral ones terminating atove on the vellow propoteal spots.

Paratypes. 2 ㅇ ㅇ ; same data as type, but Angust 1 and 8, 1957 (K. V. Krombein) [KVK]. 1 of Arlington, Va.; July 11, 195t (K. V. Krombein) [KVK]. 2 ㅇ \& ; Princeton, Mercer (o., N. J.; Jume 9, 1946 and August $2,19+1$ (the latter pinned with an adult membracid, spissistilus constans (W'k.)) (K. W. ('ooper) [USNM]. 1 of: Shokan,
 nell Chiversity Cambus, Ithaca, Tompkins Co., N. Y.: Jume 18 and .July 6, 19:37 (P. I’. Babiy) (CU|. 1 of : Ithaca, N. Y'. (Chittenden) [USNM]. 1 우: Ithaca, N. Y., July 14, 1917 (E. C. Van Dyke) [Cal. Acad. Sci]. 1 \& ; Ringwood, Ithaca, N. Y.; July 5, 1920 [CU]. 1 of; Forest Lawu Cemetery, Buffalo, Erie Co.. N. Y.; June 20, 19:3t (K. V. Krombein) [KVK]. 1 ô ; Hartford, Martford Co., Coun.; June 12, 1895 [U. C'alif., Davis]. 1 o ; New Hampshire [USNM]. 1 ó ; Rondean Park, Kent Co., Ont.; Jume 28, 19:6 (4. Sterskal) [C. Mich.]. 1 of Sun Arbor, Washtenaw ('o., Mich.; July 27, 1935 [U. Calif., Davis]. 1 o ; Detroit, Wayne ('o., Mith.; June 14, 19:36 (G. Steyskal) [U. Mieh.]. 1 오 : Ohmsted ('o., Minn. (C. N. Minslie) [USNM]. 1 of ; Baldwin, Douglas Co., Kans.; June (.J. C. Bridwell) [USNM]. 1 if: Carns, Rock Co., Nebr.; July 1, I90: (W. 1). Pierce) [U. Nebr.].

Female paratypes range from 8.5 to 11.5 mm . in length There is $n 0$ significant variation in details of the seulpture except that rugae may cover only the basal half of the propodeal enclosure. Likewise, there is very little variation in the coloration, the chief difference being a slight reduction in extent of the yellow markings in a conple of the specimens. The male paratypes are much like the allotype in coloration, but the rugae on posterior surface of propodeum do not extend quite as high ; they range from 8 to 9.5 mm, in length.

[^0]:    ${ }^{1}$ The Symmorphus larva in cell - died several days later. Howerer, there can be no reasonable doubt as to the identity of the host wasp. I have reared Symmorphus canadonsis from other trap nests containing the same prey and from the same station, and I know of no other wasp which press on larvae of Chatep"s dorsalis.
